

Priority queue over T^*

types ranked by Weeds-precision in-degree (τ); ties within δ share a band -- seeds, if any, pinned at the top

↓ *pop highest-priority node*

Compare vs. candidates at current level

similarity-ranked batches of size B ; escalate up to E times whenever a batch returns "none"

LLM decision -- one of five outcomes

synonym -- merge into the matched candidate

→ *next node*

child of -- descend into that candidate's own children

→ *recurse: back to "compare" one level deeper*

parent of -- insert above; retroactively reparent it

→ *corrects an earlier too-shallow attachment; settle, next node*

same class -- synthesize a new shared parent

→ *new node re-enters the priority queue*

none -- no candidate matches, even at the last batch

→ *settle: new root (top level) or child of anchor; next node*

Depth bound $D_{\max}$

exceeds it → defer into `unresolved_children`, never forced

repeat until the priority queue is empty
