Priority queue over T*
types ranked by Weeds-precision in-degree (τ); ties within δ share a band -- seeds, if any, pinned at the top
pop highest-priority node
Compare vs. candidates at current level
every current sibling at this level, shown at once (consolidated first below if the level exceeds B)
LLM decisions -- parent check, then child check
parent check: synonym -- merge into the candidate
→ next node
e.g. movie vs {film} → merge movie into film
parent check: match -- descend into its children
→ recurse: back to "compare" one level deeper
e.g. documentary film vs {audiovisual work} → descend
child check: match -- reparent above it
→ corrects an earlier too-shallow attachment; settle, next node
e.g. film subsumes documentary film → reparent under film
consolidate -- only when level size > B
→ groups TRUE siblings under a parent; never a per-pair action
e.g. war film + action film → group → genre film
none -- no match in parent or child check
→ settle: new root (top level) or child of anchor; next node
e.g. war film vs {documentary film} → settles as sibling
Depth bound Dmax
exceeds it ⇒ defer into unresolved_children, never forced
repeat until the priority queue is empty
